	<p>Data were used from a Danish prospective cohort study originally designed to investigate associations between diet and other lifestyle exposures and cancer in middle-aged individuals. From December 1993 to May 1997, 160,725 Danish women and men aged 50 to 64 years were invited to participate in the Diet, Cancer and Health study. Eligible cohort members were born in Denmark and not previously diagnosed with cancer. In all, 27,178 men and 29,875 women participated in the study (response rate 35%).</p> <p>For the present study of drinking pattern and risk of alcoholic cirrhosis, the authors excluded subjects diagnosed with alcoholic cirrhosis before baseline (n=86). Also excluded were subjects with missing information on alcohol amount (n=105), smoking (n=27), education (n=27), and waist circumference (n=50), and participants who reported conflicting answers on alcohol amount and frequency (n=236) or smoking status and tobacco use (n=7).</p> <p>At baseline, participants were asked to recall the average amount per week of specific types of alcohol they consumed when they were 20–29, 30–39, 40–49, and 50–59 years old and the number of drinking days per week over the years.</p>
Prognostic variable(s)	Alcohol use (categorical: lifetime abstainers, current abstainers, and five categories of drinkers with up to 7 drinking days per week): on the basis of questionnaire items about alcohol use at initial examination
Confounders	<ul style="list-style-type: none"> <li>• age</li> <li>• sex</li> <li>• length of education</li> <li>• waist circumference</li> <li>• smoking</li> </ul>
Outcomes and effect sizes	<p>Participants were observed from baseline until diagnosis of alcoholic cirrhosis (n=342), migration (n=337), loss to follow-up (n=2), death from other causes (n=8,132), or 31<sup>st</sup> December 2011 (end of follow-up), whichever came first. Information on liver cirrhosis was obtained from the National Patient Register and the Danish Register of Causes of Death. The former was established in 1977 and contains data on all somatic hospital admissions and, since 1995, data on outpatient contacts as well. The Danish register of Deaths contains information on all causes of death in Denmark. In both registries, diagnoses are recorded according to the 8<sup>th</sup> and 10<sup>th</sup> international classification of diseases (codes for alcoholic cirrhosis, ICD-8: 571.0 and ICD-10: K70.3, and codes for unspecified cirrhosis, ICD-8: 571.9, 456.0, 785.3 and ICD-10: 185.0, 185.9, K74.6, R18.9), and the validity is considered to be high. The data on vital status and migration were obtained from the Danish Civil Registration system.</p> <p>For the hazard ratios of developing alcoholic cirrhosis, the reference group for alcohol use was 2–4 drinking days per week. Multivariate analysis used the Cox proportional hazards model (CI) adjusted for the above mentioned confounders.</p> <p><b>Men who received diagnosis of alcoholic cirrhosis n=257</b></p>

Study type and analysis	Prospective cohort.
Number of participants and characteristics	Baseline data were collected from 1971–1974 as part of the first National Health and Nutrition Examination Survey (NHANES I) and included interviews, physical examinations, and laboratory investigations on 14,407 participants aged 25–74 years in the United States. The NHANES I participants were subsequently followed up in 1982–1984, 1986, 1987, and finally in 1992 as part of the NHANES Epidemiologic Follow-up Study

Reference	IOANNOU 2003 <sup>62</sup>
	<p>(NHEFS). Excluded participants who might have already had chronic liver disease or cirrhosis at the time of entry into the study (1227 participants who reported a history of jaundice; were found to have hepatomegaly or splenomegaly on physical examination; or had a serum albumin level less than 3 g/dl). Excluded 565 participants who either died or had a diagnosis of liver cirrhosis in their hospitalization records within the first 5 years after entry into the study (to reduce the possible effects of subclinical liver disease on BMI and fat distribution). Excluded 604 participants with missing information for any one of the variables (BMI, age, alcohol consumption, sex, race, educational attainment, household income, and geographic location in the United States).</p> <p>Final analysis n=11,465. Male/female: 4439/7026.</p> <p>Mean follow-up time of 12.9 years</p> <p>Normal weight: n=5752; overweight: n=3774; obese: n=1939</p>
Prognostic variable(s)	<p>BMI: calculated at entry into the study. BMI categorized participants into normal-weight (BMI &lt;25 kg/m<sup>2</sup>), overweight (BMI 25 to &lt;30 kg/m<sup>2</sup>), and obese categories (BMI ≥30 kg/m<sup>2</sup>)</p>
Confounders	<ul style="list-style-type: none"> <li>• age (modelled as a continuous variable)</li> <li>• alcohol consumption over the previous 12 months (modelled as a dummy variable with categories: none [which included consuming alcohol &lt;2–3 times per year], &gt;0 to 1 drink/day, &gt;1 to 2 drinks/day, and &gt;2 drinks/day)</li> <li>• sex</li> <li>• race (Caucasian, non-Caucasian)</li> <li>• education (high school graduate or not)</li> <li>• household income (modelled as a continuous-categoric variable in \$1000 intervals)</li> <li>• geographic location in the United States (modelled as a dummy variable with categories: Northeast, Midwest, South, and West).</li> </ul> <p>Models with and without adjusting for serum cholesterol level or the presence of self-reported diabetes mellitus were used to investigate whether obesity is associated with cirrhosis over and above any effect that is mediated through diabetes mellitus and hypercholesterolemia, which are risk factors for non-alcoholic steatohepatitis.</p>
Outcomes and	<p>Death or hospitalisation caused by cirrhosis.</p>

Reference	IOANNOU 2003 <sup>62</sup>																
effect sizes	<p>Specially trained NHANES I Epidemiologic Follow-up Study personnel used all available hospital records to assign the principal diagnosis as “the condition established after study to be chiefly responsible for occasioning the admission of the patient to the health care facility.” Causes of death were abstracted from the death certificates. Death or hospitalization caused by cirrhosis was defined by one of the following International Classification of Diseases, Ninth Revision diagnoses, recorded either on the death certificate or as the principal diagnosis of hospitalization: 571.2 (alcohol induced cirrhosis), 571.5 (cirrhosis without mention of alcohol), 571.6 (biliary cirrhosis), 456.0 (oesophageal varices with bleeding), 456.1 (oesophageal varices, no mention of bleeding), 572.2 (hepatic coma), 572.3 (portal hypertension), 572.4 (hepatorenal syndrome), and 155.0 (primary liver cancer).</p> <p>The Cox proportional-hazards model was used to determine the hazard ratio comparing obese or overweight persons with normal-weight persons with respect to the risk for cirrhosis-related death or hospitalization, after adjusting for confounders. The date 5 years after the measurement of the BMI was used as time 0 in the model because the analysis was restricted to participants who remained alive and without a diagnosis of cirrhosis for at least 5 years after entry into the study.</p> <p>Adjusting for diabetes:                      Obese versus normal weight: adjusted hazard ratio 1.65 (95% CI 0.9–3.1)                      Overweight versus normal weight: adjusted hazard ratio 1.08 (95% CI 0.6–1.9)</p> <p>Not adjusting for diabetes:                      Obese versus normal weight: adjusted hazard ratio 1.69 (95% CI 1.0–3.0)                      Overweight versus normal weight: adjusted hazard ratio 1.16 (95% CI 0.7–1.9)</p> <p>The associations between BMI category and cirrhosis-related death or hospitalization were not appreciably different between men and women, between Caucasians and non-Caucasians, or between persons with serum iron saturation above or below 45% (data not shown).</p> <table border="1" data-bbox="448 1165 2049 1324"> <thead> <tr> <th data-bbox="448 1165 851 1204"></th> <th colspan="3" data-bbox="851 1165 2049 1204">Reported alcohol consumption</th> </tr> <tr> <th data-bbox="448 1204 851 1244">BMI category (adjusted HRs)</th> <th data-bbox="851 1204 1142 1244">None</th> <th data-bbox="1142 1204 1478 1244">Up to 0.3 drinks/day</th> <th data-bbox="1478 1204 2049 1244">&gt;0.3 drinks/day</th> </tr> </thead> <tbody> <tr> <td data-bbox="448 1244 851 1284">Overweight (versus normal)</td> <td data-bbox="851 1244 1142 1284">1.93 (0.7–5.3)</td> <td data-bbox="1142 1244 1478 1284">1.31 (0.4–4.2)</td> <td data-bbox="1478 1244 2049 1284">0.97 (0.5–1.8)</td> </tr> <tr> <td data-bbox="448 1284 851 1324">Obese (versus normal)</td> <td data-bbox="851 1284 1142 1324">4.10 (1.4–11.4)</td> <td data-bbox="1142 1284 1478 1324">2.48 (0.7–8.4)</td> <td data-bbox="1478 1284 2049 1324">0.80 (0.3–2.1)</td> </tr> </tbody> </table> <p>Adjusting for serum cholesterol level had almost no effect on the association between BMI category and death or hospitalization owing to cirrhosis. Outcomes and effect sizes	<p>Hospitalisation or death due to cirrhosis. Hospitalisations at Northern California Kaiser Permanente facilities were ascertained through December 1988 or until subjects left the health plan. Hospitalisation for cirrhosis was detected by computer search for a primary discharge diagnosis of International Classification of Diseases, Adapted, Eighth Revision (ICDA-8), code 571. Primary death certificate diagnoses of cirrhosis were classified by ICD-9 codes as alcoholic (ICD-9 codes 571.0-571.3) or as non-alcoholic (ICD-9 codes 571.4-571.9).</p> <p>For non-alcoholic cirrhosis, the reference group for alcohol use was lifelong non-drinkers. For alcoholic cirrhosis, there were too few non-drinkers to use this category as the reference, so the reference group for alcohol use also included persons who reported current consumption of less than one drink per day. Multivariate analysis used the Cox proportional hazards model. Outcome was described as 'relative risk'.</p> <p>Hospitalisation for alcoholic cirrhosis n=59 Drinks/day Reference: RR 1.0 Ex-drinkers: RR 5.4 1–2: RR 7.7 3–5: RR 18.2 ≥6: RR 33.1</p> <p>Hospitalisation for non-alcoholic cirrhosis n=30 Drinks/day Reference: RR 1.0 Ex-drinkers: RR 1.2 1–2: RR 0.8 3–5: RR (analysis not performed because of the small number of cases) ≥6: RR 0.8</p> <p>Death from alcoholic cirrhosis n=40 Drinks/day Reference: RR 1.0 Ex-drinkers: RR 17.1 1–2: RR 7.8</p>

Study type and analysis	Prospective cohort. Logistic regression.
Number of participants and characteristics	792 subjects from a longitudinal cohort study conducted in Gothenburg, during a 40-year study period. In 1963 all men born in 1913 on those days which were even multiples of 3 and still alive at the age of 50 were invited to participate in a longitudinal population study. None of the participants had cirrhosis at inclusion.  Cirrhosis was classified as patients with a diagnosis of 571,00-99, 571A-X and K70.2-3, K71.7, K74.0-6 on The Swedish Hospital Discharge Register based on compulsory reports on diagnoses for all hospitalised patients in Sweden (using the Swedish version of the International Classification of Diseases).
Prognostic variable(s)	1. Alcohol abuse I (individuals who have sought help for alcohol addiction, been arrested for drunkenness or had been provided with institutional care by social authorities) 2. Alcohol abuse II (self-reported as having alcohol problems and/or daily alcohol consumption). 3. BMI
Confounders	BMI, triglycerides, two definitions of alcohol abuse
Outcomes and effect sizes	Endpoint: patients who were hospitalised and/or died with a diagnosis of liver cirrhosis.  14 patients developed cirrhosis (established histopathologically in 11 and 3 had typical radiological findings with clinical complications).  'Model 1' results (Alcohol abuse 1 definition):
