Created: September 19, 2019.

Summary

Clinical characteristics

Retinal vasculopathy with cerebral leukoencephalopathy and systemic manifestations (RVCL-S) is a small-vessel disease that affects highly vascularized tissues including the retina, brain, liver, and kidneys. Age of onset is often between 35 and 50 years. The most common presenting finding is decreased visual acuity and/or visual field defects. Neurologic manifestations may include hemiparesis, facial weakness, aphasia, and hemianopsia. Migraines and seizures are less frequently described. Renal manifestations may include mild-to-moderate increase in serum creatinine and mild proteinuria; progression to end-stage renal disease (ESRD) is uncommon. Hepatic manifestations frequently include mildly elevated levels of alkaline phosphatase and gamma-glutamyltransferase (GGT). Less common findings include psychiatric disorders, hypertension, mild-to-moderate anemia, and Raynaud phenomenon.

Diagnosis/testing

The diagnosis of RVCL-S is established in a proband with suggestive findings and a heterozygous pathogenic variant in *TREX1* identified by molecular genetic testing.

Management

Treatment of manifestations: Retinal vasculopathy may be treated with laser therapy, which may also prevent and slow the progression of visual impairment; macular edema may respond to bevacizumab; ESRD may require renal replacement therapy (including renal transplantation); corticosteroid therapy may be considered for those

with cerebral vasogenic edema; standard treatment for glaucoma, hypertension, migraine headaches, seizure disorders, hypothyroidism, anemia, Raynaud phenomenon, and psychiatric disorders.

Surveillance: Ophthalmologic evaluation, blood pressure assessment, renal function tests (serum creatinine, BUN, and urinalysis to include creatinine and protein content), liver function tests (AST, ALT, alkaline phosphatase, GGT, serum albumin), TSH and free T4, and complete blood count annually starting in the fourth decade or as appropriate based on symptoms; annual assessment of cognition and psychiatric manifestations.

Agents/circumstances to avoid: Intravenous tissue-type plasminogen activator therapy for acute ischemic stroke is not warranted, as there is no proof that neurologic manifestations are caused by occluded large blood vessels and the risk of complications is assumed to be higher in affected individuals.

Evaluation of relatives at risk: It is appropriate to evaluate the genetic status of apparently asymptomatic older and younger at-risk relatives of an affected individual by molecular genetic testing of the *TREX1* pathogenic variant in the family in order to identify as early as possible those who would benefit from prompt initiation of treatment and preventive measures.

Genetic counseling

RVCL-S is inherited in an autosomal dominant manner. Most individuals diagnosed with RVCL-S have an affected parent. However, disease onset and severity vary considerably even within the same family. The offspring of an individual with RVCL-S are at a 50% risk of inheriting the *TREX1* pathogenic variant. If the pathogenic variant in the family is known, prenatal testing for pregnancies at increased risk for RVCL-S and preimplantation genetic testing are possible; however, such testing for adult-onset disorders is uncommon.

Diagnosis

There are no consensus clinical diagnostic criteria for retinal vasculopathy with cerebral leukoencephalopathy and systemic manifestations (RVCL-S).

Suggestive Findings

RVCL-S **should be suspected** in individuals with the following findings [Stam et al 2016, Pelzer et al 2019].

Major features

- Vascular retinopathy typically manifesting as decreased visual acuity and/or visual field defects
- Focal and/or global brain dysfunction and brain MRI abnormalities
 - Focal neurologic signs can include but are not limited to hemiparesis, facial weakness, aphasia, and hemianopsia.
 - Global brain dysfunction may manifest as progressive cognitive impairment.
 - Brain MRI abnormalities are restricted to the white matter (see Clinical Characteristics, Neurologic Features).
- Family history of middle-age onset of disease manifestations consistent with an autosomal dominant inheritance pattern

Note: Absence of a known family history of similarly affected individuals does not preclude the diagnosis.

Supportive features

- Calcifications on brain CT scan, typically not present in healthy controls
- Nonspecific MRI white matter lesions that occur more frequently than expected given the age of the individual

- Microvascular liver disease, manifested by modest elevations of alkaline phosphatase and gamma-glutamyltransferase
- Microvascular kidney disease, typically manifested by a mild-to-moderate increase in serum creatinine or by proteinuria

Likely associated features

- Anemia consistent with blood loss and/or chronic disease (typically normocytic and normochromic)
- Microscopic gastrointestinal bleeding
- Hypertension
- Migraine with or without aura
- Raynaud phenomenon (typically mild)
- Subclinical hypothyroidism

Establishing the Diagnosis

The diagnosis of RVCL-S is **established** in a proband with suggestive findings and a heterozygous pathogenic variant in *TREX1* identified by molecular genetic testing (see Table 1).

Molecular genetic testing approaches can include **single-gene testing** and use of a **multigene panel**:

- **Single-gene testing.** Sequence analysis of *TREX1* detects small intragenic deletions/insertions and missense, nonsense, and splice site variants; typically, exon or whole-gene deletions/duplications are not detected. Perform sequence analysis of *TREX1*.
- **A multigene panel** that includes *TREX1* and other genes of interest (see Differential Diagnosis) is most likely to identify the genetic cause of the condition while limiting identification of variants of uncertain significance and pathogenic variants in genes that do not explain the underlying phenotype. Note: (1) The genes included in the panel and the diagnostic sensitivity of the testing used for each gene vary by laboratory and are likely to change over time. (2) Some multigene panels may include genes not associated with the condition discussed in this *GeneReview*. (3) In some laboratories, panel options may include a custom laboratory-designed panel and/or custom phenotype-focused exome analysis that includes genes specified by the clinician. (4) Methods used in a panel may include sequence analysis, deletion/duplication analysis, and/or other non-sequencing-based tests.

For an introduction to multigene panels click [here](#). More detailed information for clinicians ordering genetic tests can be found [here](#).

Note: At the Leiden University Medical Center, a panel of genes is used to screen for pathogenic variants that cause cerebral angiopathies and adult-onset leukoencephalopathies. New pathogenic variants that cause these disorders continue to be discovered; click [here](#) for more information.

Table 1. Molecular Genetic Testing Used in Retinal Vasculopathy with Cerebral Leukoencephalopathy and Systemic Manifestations

Gene ¹	Method	Proportion of Probands with a Pathogenic Variant ² Detectable by Method
<i>TREX1</i>	Sequence analysis ³	Estimated >99% ^{4, 5}
	Gene-targeted deletion/duplication analysis ⁶	Unknown ⁷

1. See Table A. Genes and Databases for chromosome locus and protein.

2. See Molecular Genetics for information on allelic variants detected in this gene.

3. Sequence analysis detects variants that are benign, likely benign, of uncertain significance, likely pathogenic, or pathogenic. Variants may include small intragenic deletions/insertions and missense, nonsense, and splice site variants; typically, exon or whole-gene deletions/duplications are not detected. For issues to consider in interpretation of sequence analysis results, click [here](#).

4. The identification of a heterozygous pathogenic variant in *TREX1* is required for the diagnosis RVCL-S. The proportion of individuals with suggestive features of RVCL-S who do not have an identifiable heterozygous pathogenic variant in *TREX1* has not been systematically studied.

5. To date, all pathogenic variants in *TREX1* that cause RVCL-S have been frameshift variants in the region encoding the C terminus of the protein.

6. Gene-targeted deletion/duplication analysis detects intragenic deletions or duplications. Methods used may include quantitative PCR, long-range PCR, multiplex ligation-dependent probe amplification (MLPA), and a gene-targeted microarray designed to detect single-exon deletions or duplications.

7. No data on detection rate of gene-targeted deletion/duplication analysis are available.

Clinical Characteristics

Clinical Description

Clinical information about RVCL-S is summarized from the following reports of individuals with molecularly confirmed RVCL-S: Storimans et al [1991], Terwindt et al [1998], Cohn et al [2005], Richards et al [2007], Winkler et al [2008], Mateen et al [2010], Gruver et al [2011], Schuh et al [2014], Dhamija et al [2015], DiFrancesco et al [2015], Stam et al [2016], Vodopivec et al [2016], Carra-Dalliere et al [2017], Hardy et al [2017], and Pelzer et al [2019]. The numerators and denominators in this section are derived from the study by Stam et al [2016], which included 11 affected families and is the largest study to date on RVCL-S.

RVCL-S is a small-vessel disease that systemically affects various highly vascularized organs. Affected individuals develop retinal vasculopathy and neurologic symptoms, in addition to other systemic manifestations including impaired liver and renal function.

Clinical presentation is variable; onset is often between ages 35 and 50 years, with a mean age at clinical diagnosis of 42.9 years (SD ±8.3, range 25-61 years). Life expectancy is decreased; the average age of death is 53.1 years (SD ±9.6, range 32-72). Cause of death is frequently pneumonia or sepsis in the setting of general debilitation. For clinical course see Figure 1.

Ophthalmologic Features

Symptoms

- Symptoms caused by retinal vasculopathy are the most common presenting finding in individuals with RVCL-S but can also develop later in the disease course.
- Affected individuals often notice decreased visual acuity and/or visual field defects. A gradual worsening often occurs and affected individuals can become legally blind.

Signs

Figure 1. Clinical course of RVCL-S

Adapted from Pelzer et al [2019]

- All individuals with a heterozygous pathogenic variant in *TREX1* will develop vascular retinopathy at some point.
- The retinopathy is characterized in the early stages by telangiectasias, microaneurysms, and cotton wool spots.
- In later stages perifoveal capillary obliterations and neovascularizations appear.
- Macular edema and neovascular glaucoma may develop as a complication of vascular retinopathy.

Neurologic Features

Symptoms

- **Focal neurologic symptoms** were reported in 40/72 individuals. These symptoms occurred more frequently in those with retinal vasculopathy and/or brain lesions (40/59). Manifestations include but are not limited to hemiparesis, facial weakness, aphasia, and hemianopsia.

- **Cognitive impairment** has been described in 32/57 affected individuals with retinal vasculopathy and/or brain lesions. This ratio is higher (21/28) in those with more disease symptoms, implying a progressive decline in cognition. Apathy, irritability, and difficulties with memory and judgment have also been reported.
- **Migraine** occurred in 24/41 individuals in whom other manifestations of the disease (retinal vasculopathy and/or brain lesions) were present. Of 16 deceased individuals, 12 had a history of migraine at some point in their life; further clinical details are unavailable.
- **Seizures** occurred in 9/66 affected individuals. Generalized as well as partial sensomotoric seizures have been described.

Signs on neuroimaging. Three types of lesions have been observed frequently on brain MRI scans:

- **Focal, non-enhancing T₂-hyperintense lesions** scattered throughout the periventricular and deep white matter (at an age when nonspecific age-related white matter hyperintensities are infrequent)
- **Punctate T₂-hyperintense white matter lesions** with nodular enhancement
- **Hyperintense mass lesions on T₂ and hypointense lesions on T₁-weighted images**, enhanced with gadolinium contrast, and often surrounded by extensive edema. Hemorrhages are rarely reported. Occasionally, restricted diffusion, most often centrally, is observed and is referred to as a "pseudotumor." These lesions:
 - Have been reported in 36/51 individuals with a heterozygous pathogenic variant in *TREX1*, most often in later stages of the disease;
 - Are most frequently localized in the frontoparietal lobe but are occasionally found in other regions;
 - Often lead to displacement of adjacent structures and sulci effacement;
 - Can increase in size, remain stable, or diminish;
 - Are associated with calcifications on CT scan.

Renal Disease

Renal disease has been demonstrated in 22/44 affected individuals. It is typically characterized by a mild-to-moderate increase in serum creatinine and mild proteinuria but may be severe (stage IV kidney disease) and fatal in some families. While the progression of the renal disease of RVCL-S requires further study, in most cases the renal manifestations are progressive; however, there is tremendous variability in the rate of renal decline.

Liver Disease

Liver disease was present in 28/40 affected individuals and usually manifests as mildly elevated levels of alkaline phosphatase and gamma-glutamyltransferase (GGT).

Hypothyroidism

Subclinical hypothyroidism was found to be part of the disease course in a recent cross-sectional study. Of the 19 affected individuals older than age 40 years, seven had subclinical hypothyroidism.

Psychiatric Symptoms

Psychiatric manifestations were present in 26/62 affected individuals and may include depression, psychosis, anxiety, and other psychiatric problems.

Other

Additional findings may include the following:

- Hypertension (present in 30/52 individuals)
- Mild-to-moderate anemia that is typically normocytic and normochromic

- Microscopic gastrointestinal bleeding resulting in anemia (present in 25/34 affected individuals)
- Raynaud phenomenon, which is typically mild (present in approximately 31/73 individuals with a heterozygous pathogenic variant in *TREX1*)
- Avascular necrosis of the femoral head (2 individuals)
- (Hypertensive) cardiomyopathy (3 individuals)
- Macular skin rash and punctate skin lesions (3 individuals)

Pathology

Histologic abnormalities have been demonstrated in all organs involved in RVCL-S, including the following.

Retina

- Scattered microinfarcts
- Thickened hyalinized retinal arterial walls
- Focal areas of disruption of the ganglion cell layer and inner nuclear layer

Brain

- Multiple – often confluent – foci of ischemic necrosis of white matter
- Vasculopathy: vessel wall thickening and luminal stenosis; telangiectasias
- A modest chronic inflammatory cell infiltrate in some individuals
- Focal calcifications and reactive astrocytosis
- Myelin loss

Kidney

- Renal arteriolosclerosis
- Focal or diffuse glomerulosclerosis

Liver

- Nodular regenerative hyperplasia
- Micro- and macrovesicular steatosis
- Periportal inflammation
- Bridging and portal fibrosis

Genotype-Phenotype Correlations

To date, all pathogenic variants have been frameshift variants in the region of *TREX1* encoding the carboxyl terminus of TREX1 (see Molecular Genetics).

To date no genotype-phenotype correlations have been observed.

Penetrance

Penetrance of RVCL-S is age dependent; however, it is thought that all individuals with a heterozygous pathogenic *TREX1* variant will develop features of this condition if they live long enough.

Nomenclature

Previous descriptions of families with cerebroretinal vasculopathy (CRV); hereditary vascular retinopathy (HRV); hereditary endotheliopathy, retinopathy, nephropathy, and stroke (HERNS); hereditary systemic angiopathy (HSA); and retinal vasculopathy with cerebral leukodystrophy (RVCL) represent early reports of RVCL-S.

Prevalence

Currently, fewer than 25 families with RVCL-S are known. However, RVCL-S is most likely underdiagnosed because physicians are generally unfamiliar with the disorder. For example, in the Netherlands alone three unrelated families have been identified because of increased awareness of this condition. The widespread availability of exome and genome sequencing techniques likely also contribute to increased recognition of RVCL-S.

Genetically Related (Allelic) Disorders

Table 2 includes other phenotypes caused by pathogenic variants in *TREX1*, the gene associated with retinal vasculopathy with cerebral leukoencephalopathy and systemic manifestations (RVCL-S).

Table 2. Allelic Disorders

Gene	Phenotype ¹
<i>TREX1</i>	Aicardi-Goutières syndrome ²
	Chilblain lupus (OMIM 610448) ²
	Susceptibility to systemic lupus erythematosus (OMIM 152700) ²
	Scleroderma (systemic sclerosis) [Hughes et al 2017]

1. See hyperlinked *GeneReview*, OMIM phenotype entry, or cited reference for more information.

2. Pathogenic variants typically affect one of three exonuclease domains of *TREX1* and lead to a reduced or ablated exonuclease activity [Lehtinen et al 2008].

In addition, two individuals with *TREX1* heterozygous pathogenic missense variants were found to have early-onset cerebrovascular disease, without the presence of typical RVCL-S lesions on MRI brain or typical RVCL-S features even though they were older than age 40 years [Pelzer et al 2013].

Differential Diagnosis

Due to the systemic nature of retinal vasculopathy with cerebral leukoencephalopathy and systemic manifestations (RVCL-S), the differential diagnosis is quite broad. Following are differential diagnoses specifically for the characteristic brain findings and vascular retinopathy seen in RVCL-S. For other inherited disorders with phenotypic similarities see Table 3.

Focal and/or Global Brain Dysfunction / MRI Brain Abnormalities

Focal and/or global brain dysfunction and MRI brain abnormalities (intracerebral mass lesions and white matter abnormalities) seen in RVCL-S can be similar to intracranial neoplasm, multiple sclerosis, multi-infarct dementia, and central nervous system vasculitis. In these disorders other organs are usually not affected. Moreover, these conditions do not typically follow an autosomal dominant inheritance pattern.

- In sarcoidosis and systemic lupus erythematosus (SLE) (see Table 3) there can be focal and/or global brain dysfunction as well as involvement of multiple organs, as is seen in RVCL-S.
- With sarcoidosis, however, there is frequent involvement of the lungs and skin. No lesions in the lungs have been described in individuals with RVCL-S and skin lesions are not frequently reported [Hardy et al 2017].

Vascular Retinopathy

Vascular retinopathy can occur as a long-term complication of diabetes mellitus and hypertension:

- As the vascular retinopathy in RVCL-S is usually observed at a relatively young age (retinopathy has been found in the third decade of life) it is unlikely to be a complication of hypertension or diabetes mellitus, even in those with RVCL-S who have co-occurrence of hypertension or diabetes.
- Vascular retinopathy can also be caused by systemic lupus erythematosus, sarcoidosis, and ophthalmologic infections (which are outside of the scope of this *GeneReview*).
- In Susac syndrome, vascular retinopathy and encephalopathy are part of the symptomatology, as is hearing loss, but hearing loss is very rare in RVCL-S. The pattern of white matter lesions seen on MRI may also help to distinguish the two conditions.

Table 3. Inherited Disorders to Consider in the Differential Diagnosis of RVCL-S

Differential Diagnosis Disorder	Gene(s)	MOI	Clinical Features of the Differential Diagnosis Disorder	
			Overlapping w/RVCL-S	Distinguishing from RVCL-S
CADASIL	<i>NOTCH3</i>	AD	<ul style="list-style-type: none"> • Focal neurologic symptoms • Progressive cognitive decline • Migraine • Mood disturbances • Apathy • White matter lesions on brain imaging • Positive family history 	<ul style="list-style-type: none"> • Clinical involvement limited to the brain • The pattern of white matter lesions on brain imaging differs from that in RVCL-S.
CARASAL	<i>CTSA</i>	AD	<ul style="list-style-type: none"> • Ischemic stroke • Progressive cognitive decline • Extended white matter lesions on brain imaging • Hypertension 	Hemorrhagic strokes occur frequently in CARASAL.
CARASIL	<i>HTRA1</i>	AR	<ul style="list-style-type: none"> • Stepwise deterioration in brain functions • Progressive cognitive decline • Extended white matter lesions on brain imaging • Positive family history 	<ul style="list-style-type: none"> • Spasticity in lower extremities, spondylosis deformans & alopecia • AR inheritance
Fabry disease	<i>GLA</i>	XL	<ul style="list-style-type: none"> • Focal neurologic complaints • Nephropathy • Positive family history 	<ul style="list-style-type: none"> • Angiokeratomas, hypohidrosis, & corneal opacity • Onset usually in childhood or adolescence • XL inheritance; heterozygous females can be asymptomatic w/ normal life span.
Neurofibromatosis 1	<i>NF1</i>	AD	<ul style="list-style-type: none"> • Focal neurologic symptoms w/mass lesions on brain imaging • Seizures • Migraine • Positive family history 	<ul style="list-style-type: none"> • Café au lait macules, neurofibroma, plexiform neurofibroma, freckling in axillary or inguinal regions, optic glioma, Lisch noduli, & distinctive osseous lesions • Pattern of lesions on brain imaging differs from that seen in RVCL-S.

Table 3. continued from previous page.

Differential Diagnosis Disorder	Gene(s)	MOI	Clinical Features of the Differential Diagnosis Disorder	
			Overlapping w/RVCL-S	Distinguishing from RVCL-S
Systemic lupus erythematosus (OMIM 152700)	<i>CTLA4</i> <i>DNASE1</i> <i>FCGR2A</i> <i>FCGR2B</i> <i>PTPN22</i> <i>TREX1</i>	AD ¹	<ul style="list-style-type: none"> Nephropathy Anemia Retinopathy Mood disorders Cognitive complaints Seizures Liver disease 	<ul style="list-style-type: none"> Often no genetic pathogenic variant found Features of vasculitis can occur, specifically cutaneous abnormalities, oral or nasal ulcers, alopecia, & arthritis. Often associated w/↑ ANAs, anti-dsDNA; anti-Smith antibodies &/or antiphospholipid antibodies (anticardiolipin immunoglobulin or lupus anticoagulant)
Tuberous sclerosis complex	<i>TSC1</i> <i>TSC2</i>	AD	<ul style="list-style-type: none"> Multisystem disorder involving brain, kidney, & eye Focal neurologic symptoms Seizures Mass lesions on brain imaging Positive family history 	<ul style="list-style-type: none"> Formation of hamartomas & skin & lung lesions Many patients are diagnosed as children, but it is not uncommon for adults to be diagnosed.

AD = autosomal dominant; ANAs = antinuclear antibodies; AR = autosomal recessive; CADASIL = cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy; CARASAL = cathepsin A-related arteriopathy with strokes and leukoencephalopathy; CARASIL = cerebral autosomal recessive arteriopathy with subcortical infarcts and leukoencephalopathy; dsDNA = double-stranded DNA; MOI = mode of inheritance; XL = X-linked

1. Most frequently, no genetic cause is identified.

Management

Evaluations Following Initial Diagnosis

To establish the extent of disease and needs of an individual diagnosed with retinal vasculopathy with cerebral leukoencephalopathy and systemic manifestations, the evaluations summarized in Table 4 (if not performed as part of the evaluation that led to the diagnosis) are recommended.

Table 4. Recommended Evaluations Following Initial Diagnosis in Individuals with RVCL-S

System/Concern	Evaluation	Comment
Eyes	Ophthalmologic evaluation	Assess for signs of retinopathy, macular edema, & glaucoma.
Cardiovascular	Blood pressure	Assess for hypertension.
Renal	Renal function tests ¹	Consider referral to nephrologist for those w/significant renal insufficiency &/or hypertension.
Hepatology	<ul style="list-style-type: none"> Liver enzymes ² & serum albumin Consideration of serum lactate dehydrogenase levels, coagulation studies, & bilirubin concentration 	Consider referral to gastroenterologist for those w/ significantly altered liver enzymes or ↓ liver function.

Table 4. continued from previous page.

System/Concern	Evaluation	Comment
Neurologic	Assess cognitive function.	Consider referral to neurologist &/or a neuropsychological evaluation.
	Assess for signs & symptoms of migraines.	Consider referral to neurologist.
	EEG if seizures are suspected	
	Assess for focal neurologic complaints.	Refer to neurologist, if present.
Endocrinologic	Thyroid function ³	Refer to endocrinologist, if clinically significant
Hematologic	Complete blood count	To assess for anemia; consider referral to gastroenterologist for possible occult GI bleeding.
Rheumatologic	Assess for signs & symptoms of Raynaud phenomenon.	
Psychiatric	Assess for psychiatric symptoms. ⁴	Consider psychiatric consultation.
Other	Consultation w/clinical geneticist &/or genetic counselor	

1. Serum creatinine, BUN, and urinalysis (to include creatinine and protein content)

2. Aspartate transaminase (AST), alanine transaminase (ALT), alkaline phosphatase, gamma-glutamyltransferase (GGT)

3. TSH and free T4

4. Findings may include depression, psychosis, anxiety, or other psychiatric diagnoses.

It is crucial that unnecessary diagnostic tests not be undertaken. Biopsies of the brain, kidney, or liver are not required in individuals with RVCL-S and do not appear to provide additional prognostic or treatment information.

Treatment of Manifestations

Table 5 summarizes treatment for the manifestations of an individual diagnosed with RVCL-S.

Table 5. Treatment of Manifestations in Individuals with Retinal Vasculopathy with RVCL-S

Manifestation/Concern	Treatment	Considerations/Other
Visual impairment	Retinal laser therapy	Can prevent & slow down progression of retinal involvement that causes visual impairment
Macular edema	Bevacizumab	
Elevated eye pressure / Glaucoma	Standard treatment	
Hypertension	Standard treatment	May prevent further damage to involved organs
Renal insufficiency	Standard treatment of hypertension	Refer to nephrologist.
	Renal replacement therapy (incl transplantation) may be considered in severe cases for those w/end-stage renal disease.	
Liver function abnormalities	There is no treatment for liver function abnormalities.	Monitor to prevent complications associated w/liver fibrosis & to exclude other causes. ¹
Cerebral vascular edema	Consider corticosteroid therapy. ²	May reduce cerebral vasogenic edema but does not appear to treat the underlying lesion
Migraine	Standard treatment	
Seizure disorder	Standard treatment w/antiepileptic drugs	Refer to neurologist.

Table 5. continued from previous page.

Manifestation/Concern	Treatment	Considerations/Other
Hypothyroidism	Thyroid replacement therapy	
Anemia	Standard treatment	Intravenous iron therapy (& in rare cases blood transfusion) may be necessary.
Raynaud phenomenon	Standard treatment	
Psychiatric concerns	Standard treatment	Refer to psychiatrist or neuropsychologist.

1. When not properly monitored, affected individuals are frequently given incorrect diagnoses and often receive advice to stop drinking alcohol or stop their medication, while this is not required.

2. Intravenous methylprednisolone followed by an oral corticosteroid treatment

Surveillance

There are currently no consensus guidelines for monitoring individuals with RVCL-S. However, close monitoring is recommended. The frequency of monitoring depends on the manifestations and rate of disease progression (see Table 6).

Table 6. Recommended Surveillance for Individuals with RVCL-S

System/Concern	Evaluation	Frequency (Minimum)
Eyes	Ophthalmologic evaluation	Annually starting in 4th decade or as appropriate based on symptoms
Cardiovascular	Blood pressure evaluation	
Renal	Renal function tests ¹	
Endocrinologic	TSH and free T4	
Hematologic	Complete blood count	
Hepatology	Liver enzymes ² & serum albumin	Annually starting in the 4th decade
Neurologic	Assessment of cognition	Annually or as appropriate based on symptoms starting after diagnosis
Psychiatric	Assessment for psychiatric symptoms	

1. Serum creatinine, BUN, and urinalysis (to include creatinine and protein content)

2. Aspartate transaminase (AST), alanine transaminase (ALT), alkaline phosphatase, gamma-glutamyltransferase (GGT)

Agents/Circumstances to Avoid

Although there is no evidence, the authors would advise against intravenous tissue-type plasminogen activator (IV tPA) for acute ischemic stroke. There is to date no proof that the neurologic manifestations are caused by occluded large blood vessels (RVCL-S is a small vessel disease), and the risk of complications of such treatment (e.g., a secondary hemorrhage) is assumed to be higher in affected individuals.

Evaluation of Relatives at Risk

It is appropriate to evaluate the genetic status of apparently asymptomatic older and younger at-risk relatives of an affected individual by molecular genetic testing of the *TREX1* pathogenic variant in the family in order to identify as early as possible those who would benefit from prompt initiation of treatment that could benefit eyesight and prevent secondary damage due to hypertension. Furthermore, clarification of the genetic status of at-risk relatives could prevent unnecessary diagnostic tests (e.g., liver/kidney/brain biopsies).

See Genetic Counseling for issues related to testing of at-risk relatives for genetic counseling purposes.

Therapies Under Investigation

Currently, a pilot study for treating RVCL-S with aclarubicin has been started. For details, see [ClinicalTrials NCT02723448](#).

Search [ClinicalTrials.gov](#) in the US and [EU Clinical Trials Register](#) in Europe for access to information on clinical studies for a wide range of diseases and conditions.

Genetic Counseling

Genetic counseling is the process of providing individuals and families with information on the nature, mode(s) of inheritance, and implications of genetic disorders to help them make informed medical and personal decisions. The following section deals with genetic risk assessment and the use of family history and genetic testing to clarify genetic status for family members; it is not meant to address all personal, cultural, or ethical issues that may arise or to substitute for consultation with a genetics professional. —ED.

Mode of Inheritance

Retinal vasculopathy with cerebral leukoencephalopathy and systemic manifestations (RVCL-S) is inherited in an autosomal dominant manner.

Risk to Family Members

Parents of a proband

- Most individuals diagnosed with RVCL-S have an affected parent. However, there is large variability within families in disease onset and severity.
- Some individuals diagnosed with RVCL-S have the disorder as the result of a *de novo* *TREX1* pathogenic variant [DiFrancesco et al 2015]. Because simplex cases (i.e., a single occurrence in a family) have not been evaluated sufficiently to determine if the pathogenic variant occurred *de novo*, the proportion of RVCL-S caused by a *de novo* pathogenic variant is unknown.
- Molecular genetic testing is recommended for the parents of a proband with an apparent *de novo* pathogenic variant.
- If the *TREX1* pathogenic variant found in the proband cannot be detected in the leukocyte DNA of either parent, possible explanations include a *de novo* pathogenic variant in the proband or germline mosaicism in a parent. Though theoretically possible, no instances of germline mosaicism have been reported.
- The family history of some individuals diagnosed with RVCL-S may appear to be negative because of failure to recognize the disorder in family members (RVCL-S can be misdiagnosed as multiple sclerosis, multi-infarct / frontal lobe dementia, or other organ dysfunction), early death of the parent before the onset of symptoms, or late onset of the disease in the affected parent. Therefore, an apparently negative family history cannot be confirmed unless molecular genetic testing has been performed on the parents of the proband.

Sibs of a proband. The risk to the sibs of the proband depends on the clinical/genetic status of the proband's parents:

- If a parent of the proband is affected and/or is known to be heterozygous for the *TREX1* pathogenic variant, the risk to the sibs is 50%.
- If the proband has a known *TREX1* pathogenic variant that cannot be detected in the leukocyte DNA of either parent, the recurrence risk to sibs is estimated to be 1% because of the theoretic possibility of parental germline mosaicism [Rahbari et al 2016].

- The absence of clinical manifestations in parents whose genetic status is unknown cannot be used to predict risk to sibs of a proband because of the possibility of reduced penetrance or late onset in a heterozygous parent or the theoretic possibility of parental germline mosaicism.

Offspring of a proband. Each child of an individual with RVCL-S has a 50% chance of inheriting the *TREX1* pathogenic variant.

Other family members. The risk to other family members depends on the status of the proband's parents: if a parent has the *TREX1* pathogenic variant, his or her family members may be at risk.

Considerations in families with an apparent *de novo* pathogenic variant. When neither parent of a proband with an autosomal dominant condition has the pathogenic variant identified in the proband or clinical evidence of the disorder, the pathogenic variant is likely *de novo*. However, non-medical explanations including alternate paternity or maternity (e.g., with assisted reproduction) and undisclosed adoption could also be explored.

Related Genetic Counseling Issues

See Management, Evaluation of Relatives at Risk for information on evaluating at-risk relatives for the purpose of early diagnosis and treatment.

Family planning

- The optimal time for determination of genetic risk and discussion of the availability of prenatal/preimplantation genetic testing is before pregnancy.
- It is appropriate to offer genetic counseling (including discussion of potential risks to offspring and reproductive options) to young adults who are affected or at risk.

DNA banking. Because it is likely that testing methodology and our understanding of genes, pathogenic mechanisms, and diseases will improve in the future, consideration should be given to banking DNA from probands in whom a molecular diagnosis has not been confirmed (i.e., the causative pathogenic mechanism is unknown).

Prenatal Testing and Preimplantation Genetic Testing

Once the *TREX1* pathogenic variant has been identified in an affected family member, prenatal testing for a pregnancy at increased risk and preimplantation genetic testing are possible.

Differences in perspective may exist among medical professionals and within families regarding the use of prenatal testing, particularly if the testing is being considered for the purpose of pregnancy termination rather than early diagnosis. While most centers would consider use of prenatal testing to be a personal decision, discussion of these issues may be helpful.

Molecular Genetics

Information in the Molecular Genetics and OMIM tables may differ from that elsewhere in the GeneReview: tables may contain more recent information. —ED.

Table A. Retinal Vasculopathy with Cerebral Leukoencephalopathy and Systemic Manifestations: Genes and Databases

Gene	Chromosome Locus	Protein	Locus-Specific Databases	HGMD	ClinVar
<i>TREX1</i>	3p21.31	Three prime repair exonuclease 1	Three prime repair exonuclease 1 (TREX1) @ LOVD	TREX1	TREX1

Data are compiled from the following standard references: gene from [HGNC](#); chromosome locus from [OMIM](#); protein from [UniProt](#). For a description of databases (Locus Specific, HGMD, ClinVar) to which links are provided, click [here](#).

Table B. OMIM Entries for Retinal Vasculopathy with Cerebral Leukoencephalopathy and Systemic Manifestations ([View All in OMIM](#))

192315	VASCULOPATHY, RETINAL, WITH CEREBRAL LEUKOENCEPHALOPATHY AND SYSTEMIC MANIFESTATIONS; RVCLS
606609	3-PRIME @REPAIR EXONUCLEASE 1; TREX1

Gene structure. The *TREX1* transcript [NM_033629.5](#) has two exons, the first being a short noncoding exon. Alternative splicing results in alternate transcripts. For a detailed summary of gene, transcript, and protein information see Table A.

Pathogenic variants. In RVCL-S, the sequence alterations in *TREX1* are frameshift variants typically resulting in a truncated C terminus of the TREX1 protein [Richards et al 2007, Schuh et al 2014, Dhamija et al 2015, Stam et al 2016, Vodopivec et al 2016, Carra-Dalliere et al 2017].

Normal gene product. TREX1 is a major 3'-5' exonuclease in mammals and is responsible for the removal of nucleoside monophosphates from the 3' ends of DNA [Mazur & Perrino 1999]. It has a high affinity for single-stranded DNA [Höss et al 1999]. TREX1 ([NP_338599.1](#)) contains 314 amino acid residues, which are highly conserved among species [Lee-Kirsch et al 2007]. TREX1 has three exonuclease domains in the N terminus and a C-terminal domain, which is required for its localization to the endoplasmic reticulum [Mazur & Perrino 1999, Richards et al 2007, DiFrancesco et al 2015, Hasan et al 2015]. TREX1 also appears to be involved in the regulation of oligosaccharyltransferase activity [Hasan et al 2015].

Abnormal gene product. Heterozygous frameshift pathogenic variants in the C terminus of TREX1 cause RVCL-S [Richards et al 2007, Stam et al 2016]. These are predicted to result in a truncated TREX1 protein. The exonuclease function of the protein is not affected but its subcellular localization is altered [Richards et al 2007,

DiFrancesco et al 2015, Hasan et al 2015]. Recently it was demonstrated that the C terminus of TREX1 has a role in the regulation of the oligosaccharyltransferase complex located on the endoplasmic reticulum [Hasan et al 2015]. In lymphoblasts of individuals with RVCL-S this led to an increased free glycan release that could potentially cause immune activation [Hasan et al 2015]. In light of these findings, it is especially interesting that a distinct antibody profile was demonstrated in a mouse model for RVCL-S [Sakai et al 2017]. A remaining question is how pathogenic variants in the C terminus of TREX1 cause the multisystem vasculopathy seen in individuals with RVCL-S [Stam et al 2009].

[RVCL-S patient information](#)

[RVCL research](#)

The Leiden University Medical Center has expertise in the diagnosis and treatment of RVCL-S and other cerebral hereditary angiopathies (CHA). As part of a consortium we were involved in finding the locus and gene – *TREX1* – responsible for RVCL-S. We aim to study RVCL-S disease pathology through our collaboration with world-renowned scientists and our integrated clinical, radiologic, molecular, and biological approach with this unique patient group and our transgenic mouse model, and aim to include new exciting research opportunities such as brain-on-chip development.
